

## Poisson regression models

If  $Y_i$ ,  $i = 1, \dots, n$ , are counts with means  $\mu_i$ , the standard Poisson model assumes that  $Y_i \sim \text{Pois}(\mu_i)$  with variance function

$$\text{Var}(Y_i) = \mu_i.$$

The canonical link function is the log

$$g(\mu_i) = \log(\mu_i) = \eta_i,$$

**For different observation periods/areas/volumes:**

$$Y_i \sim \text{Pois}(t_i \lambda_i)$$

Taking a log-linear model for the rates,

$$\log(\lambda_i) = \mathbf{x}_i^T \boldsymbol{\beta}$$

results in the following log-linear model for the Poisson means

$$\log(\mu_i) = \log(t_i \lambda_i) = \log(t_i) + \mathbf{x}_i^T \boldsymbol{\beta},$$

where the  $\log(t_i)$  is included as a fixed term, or *offset*, in the model.

**Poisson Log-linear Model for Count Data****Example – Storing of micro-organisms**

Bacterial concentrations (counts per fixed area) measured at initial freezing ( $-70^{\circ}\text{C}$ ) and at 1, 2, 6, 12 months.

Time	0	1	2	6	12
Count	31	26	19	15	20

Hypothesized that

$$\text{average count} \propto \frac{1}{(\text{Time})^\gamma}$$

i.e. count decays over time

**Model**

$$\text{Count} \sim \text{Pois}(\mu)$$

$$\log \mu = \beta_0 + \beta_1 \log(\text{Time})$$

Avoid problems at time 0 by using

$$\log \mu = \beta_0 + \beta_1 \log(\text{Time} + 0.1)$$

### Micro-organism Data Analysis

Model	d.f.	Deviance	$X^2$
Constant	4	7.0672	7.1532
$\log(\text{Time})$	3	1.8338	1.8203

### Analysis of deviance

Source	d.f.	Deviance	p-value
Linear Regression	1	5.2334	0.0222
Error	3	1.8338	
Total	4	7.0672	

$$\log(\mu) = 3.149 - 0.1261 \log(\text{time})$$

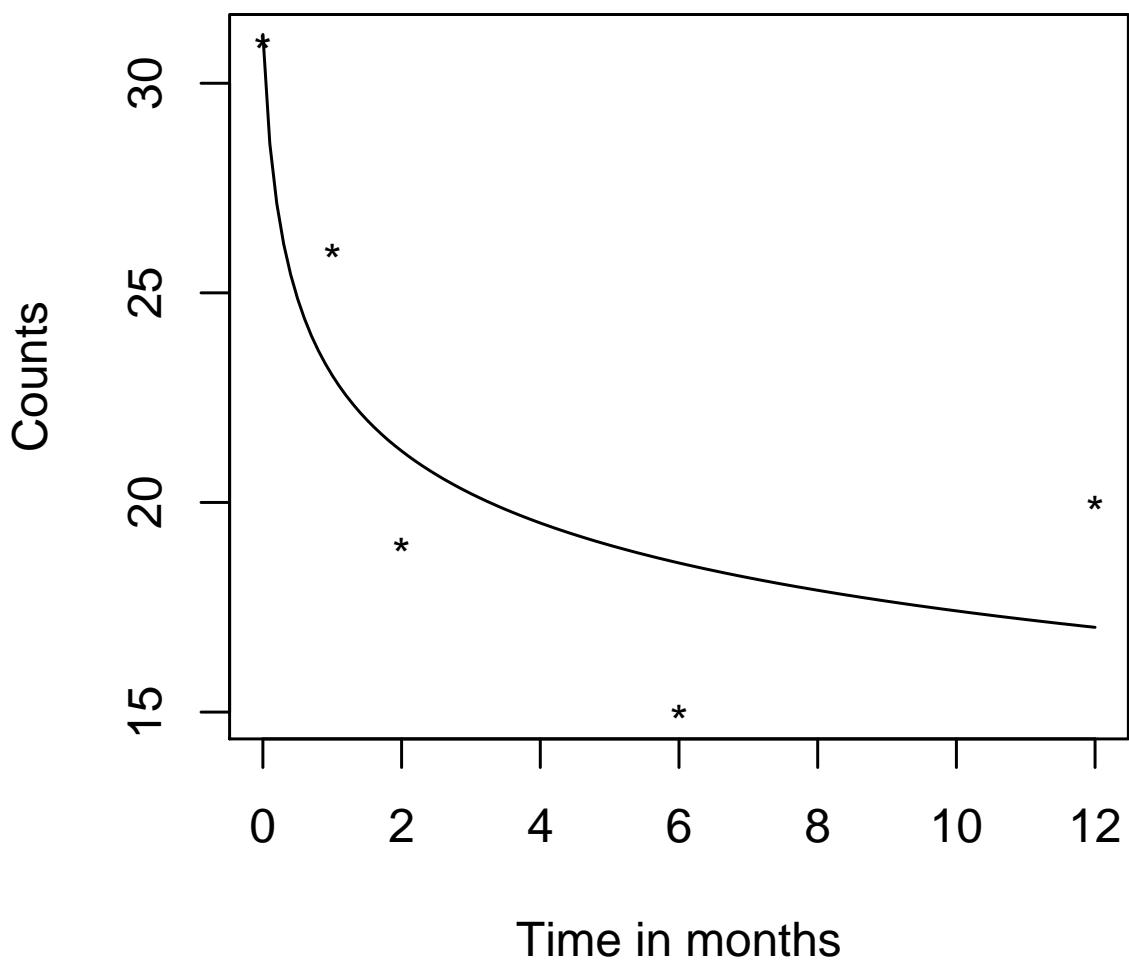

Figure 1: Bacterial Concentration: Fitted Model

## Bacterial concentrations – analysis in R

```
# *** Bacterial concentrations of stored micro-organisms
# Glim4 Manual p531
ltime <- log((tim <- c(0, 1, 2, 6, 12))+ 0.1)
lcount <- log(count <- c(31, 26, 19, 15, 20))

bacteria.dat <- data.frame(tim, count, ltime, lcount)
attach(bacteria.dat)

par(mfrow=c(1,2))

	39	0,7648	39	1,1764	34	2,3251	31	3,2228	24	4,1361		
	25	5,1371	20	6,4219	21	7,0655	12	8,7459	11	9,9817		

## Poisson Models for Rate Data

**Data:**

Counts	$C_i$
Exposure Period	$E_i$
Rate	$R_i = C_i/E_i$
Covariates	$\mathbf{x}_i$

**Modelling the Counts**

$$C_i \sim \text{Pois}(E_i \lambda_i)$$

$$\log \lambda_i = \mathbf{x}_i^T \boldsymbol{\beta}$$

$$\mathbf{E}[C_i] = \mu_i = E_i \lambda_i$$

so

$$\log \mu_i = \log E_i + \log \lambda_i$$

$$= \log E_i + \mathbf{x}_i^T \boldsymbol{\beta}$$

$\log E_i$  is included as an *offset*

## Modelling as a Rate

$$R_i = C_i / E_i$$

$$\mathbf{E}[R_i] = \frac{E_i \lambda_i}{E_i} = \lambda_i = e^{\mathbf{x}_i^T \boldsymbol{\beta}} = \mu_i^R$$

$$\text{Var}(R_i) = \frac{1}{E_i^2} \text{Var}(C_i) = \frac{E_i \lambda_i}{E_i^2} = \frac{\lambda_i}{E_i} = \frac{\mu_i^R}{E_i}$$

Use a weighted Poisson regression with weights  $E_i$ .

## Worldwide Airline Fatalities, 1976-85

Year	Fatal accidents	Passenger deaths	Passenger miles (100 million)
1976	24	734	3863
1977	25	516	4300
1978	31	754	5027
1979	31	877	5481
1980	22	814	5814
1981	21	362	6033
1982	26	764	5877
1983	20	809	6223
1984	16	223	7433
1985	22	1066	7107

## Simple Models

- Passenger miles ( $m_i$ ) as exposure variable
- Poisson log-linear model
- Linear time trend

$$\boxed{Y_i \sim \text{Pois}(m_i \lambda_i)}$$
$$\log \lambda_i = \beta_0 + \beta_1 \text{year}_i$$

### Fatal accidents:

Deviance(time trend) = 20.68

Residual Deviance = 5.46 on 8 d.f.

### Passenger deaths:

Deviance(time trend) = 202.1

Residual Deviance = 1051.5 on 8 d.f.

⇒ compounding with aircraft size

**Dilution assays**

**Example** – These data are counts of virus particles at 5 different dilutions. There are 4 replicate counts at each dilution except the last for which there are 5 counts. The aim is to estimate the number of virus particles per unit volume(Ridout, 1990).

Table 2: Counts of virus particles at 5 different dilutions

Dilution	Counts				
0.3162	13	14	17	22	
0.1778	9	14	6	14	
0.1000	4	4	3	5	
0.0562	3	2	1	3	
0.0316	2	1	3	2	2

**Aim of dilution assays:** to estimate density of particles of bacteria, viruses, fungi

Suppose

$\lambda$ : density of particles by unit volume in an initial solution

$v_i$ : volume of the  $i$ -th dilution (amount of the original suspension)

$Y_{i,j}$ : number of particles from  $i$ -th dilution,  $j$ -th replicate

$$Y_{ij} \sim P(\lambda v_i)$$

$$\mu_{ij} = \lambda v_i \Rightarrow \log(\mu_{ij}) = \log \lambda + \log(v_i) \Rightarrow \\ \log(\mu_{ij}) = \beta + \text{offset}$$

Then  $\hat{\lambda} = \exp(\hat{\beta})$  and a confidence interval for  $\lambda$  is

$$\exp[\hat{\beta} \mp 1.96 \text{s.e.}(\hat{\beta})]$$

## Virus concentration – analysis in R

```
# Dilution assay
count <- c(2,1,3,2,2, 3,2,1,3, 4,4,3,5, 9,14,6,14, 13,14,17,22)
dilui <- c(.0316,.0316,.0316,.0316,.0316, .0562,.0562,.0562,.0562, .1,.1,.1,.1,
.1778,.1778,.1778,.1778, .3162,.3162,.3162,.3162)
dilui.dat <- data.frame(dilui, count)
attach(dilui.dat)
plot(dilui, count, xlab="Dilution", ylab="Counts")

# Fitting
dilui.fit1<-glm(count ~ 1 + offset(log(dilui)), family=poisson)
anova(dilui.fit1, test="Chisq")
1-pchisq(deviance(dilui.fit1), df.residual(dilui.fit1))

# estimated density of particles of virus
# and confidence interval
conc <- exp(dilui.fit1$coef[1])
Infl <- exp(dilui.fit1$coef[1] - 1.96*summary(dilui.fit1)$coef[2])
Infl
SupL <- exp(dilui.fit1$coef[1] + 1.96*summary(dilui.fit1)$coef[2])
SupL

# Plotting
# Plotting
plot(c(0,0.32), c(0,25), type="n", xlab="Dilution", ylab="Counts")
points(dilui,count,pch="*")
x<-seq(0.01,0.32,0.01)
lp<-exp(predict(dilui.fit1,data.frame(dilui=x)))
lines(x,lp,lty=1)
```

## 2-way Contingency Table

Habitat study of lizards

		Perch		
		Diameter (in)		
		$\leq 4.0$	$> 4.0$	
Perch	$\geq 4.75$	61	41	102
Height	$< 4.75$	73	70	143
		134	111	245

Are diameter and height classifications independent?

Association measured by odds-ratio

Independence  $\implies$  odds-ratio = 1

$$\text{Observed Odds-ratio} = \frac{61 \times 70}{41 \times 73} = 1.43$$

Is this significantly different from 1?

### Log-linear models for $2 \times 2$ table

		B		
		1	2	
A	1	$m_{11}$	$m_{12}$	$m_{1.}$
	2	$m_{21}$	$m_{22}$	$m_{2.}$
		$m_{.1}$	$m_{.2}$	$m_{..}$

Model Counts  $m_{ij}$  as Poisson random variables with A and B as explanatory factors, log-link gives log-linear model.

In general, marginal distributions of A and B are not of interest.

#### Two models of interest:

- (i) A+B (independence model)
- (ii) A\*B  $\equiv$  A+B+A.B (saturated model).

(i) A+B (independence model)

$$\log \mu_{ij} = \lambda + \lambda_i^A + \lambda_j^B \quad i, j = 1, 2$$

with  $\lambda_1^A = \lambda_1^B = 0$ , i.e linear predictor

		B	
		1	2
A	1	$\lambda$	$\lambda + \lambda_2^B$
	2	$\lambda + \lambda_2^A$	$\lambda + \lambda_2^A + \lambda_2^B$

$$\hat{\lambda} = \log\left(\frac{m_{1.}m_{.1}}{m_{..}}\right)$$

$$\hat{\lambda}_2^A = \log\left(\frac{m_{2.}}{m_{1.}}\right)$$

$$\hat{\lambda}_2^B = \log\left(\frac{m_{.2}}{m_{.1}}\right)$$

### Fitted log-odds-ratio

$$\log \psi =$$

$$(\lambda + \lambda_2^A + \lambda_2^B) + \lambda - (\lambda + \lambda_2^B) - (\lambda + \lambda_2^A) = 0,$$

i.e, odds ratio  $\psi = 1 \implies$  independence model.

- A+B (margins ( $\Rightarrow$  total) reproduced)

Linear predictor

		B
A	1	2
1	$\lambda$	$\lambda + \lambda_2^B$
2	$\lambda + \lambda_2^A$	$\lambda + \lambda_2^A + \lambda_2^B$

$$\hat{\lambda}_2^A = \log\left(\frac{m_{2\cdot}}{m_{1\cdot}}\right) \quad \text{and} \quad \hat{\lambda}_2^B = \log\left(\frac{m_{\cdot 2}}{m_{\cdot 1}}\right)$$

$$\begin{aligned} m_{\cdot \cdot} &= e^{\hat{\lambda}} + e^{\hat{\lambda} + \hat{\lambda}_2^A} + e^{\hat{\lambda} + \hat{\lambda}_2^B} + e^{\hat{\lambda} + \hat{\lambda}_2^A + \hat{\lambda}_2^B} \\ &= e^{\hat{\lambda}}(1 + e^{\hat{\lambda}_2^A})(1 + e^{\hat{\lambda}_2^B}) \end{aligned}$$

$$\begin{aligned} \log m_{\cdot \cdot} &= \hat{\lambda} + \log\left(1 + \frac{m_{2\cdot}}{m_{1\cdot}}\right) + \log\left(1 + \frac{m_{\cdot 2}}{m_{\cdot 1}}\right) \\ &= \hat{\lambda} + \log\left(\frac{m_{\cdot \cdot}}{m_{1\cdot}}\right) + \log\left(\frac{m_{\cdot \cdot}}{m_{\cdot 1}}\right) \end{aligned}$$

Then,

$$\hat{\lambda} = \log(m_{\cdot \cdot} \frac{m_{1\cdot}}{m_{\cdot \cdot}} \frac{m_{\cdot 1}}{m_{\cdot \cdot}}) = \log\left(\frac{m_{1\cdot} m_{\cdot 1}}{m_{\cdot \cdot}}\right)$$

i.e,

$$e^{\hat{\lambda}} = \text{Fitted}(1, 1) = \hat{\mu}_{11} = m_{\cdot \cdot} \frac{m_{1\cdot}}{m_{\cdot \cdot}} \frac{m_{\cdot 1}}{m_{\cdot \cdot}} = np_1.p_{\cdot 1} \quad (\text{usual independence form})$$

$$\begin{aligned} \text{Fitted}(1, 2) = \hat{\mu}_{12} &= e^{\hat{\lambda} + \hat{\lambda}_2^B} = e^{\hat{\lambda}} e^{\hat{\lambda}_2^B} = m_{\cdot \cdot} \frac{m_{1\cdot}}{m_{\cdot \cdot}} \frac{m_{\cdot 1}}{m_{\cdot \cdot}} \frac{m_{\cdot 2}}{m_{\cdot \cdot}} \\ &= m_{\cdot \cdot} \frac{m_{1\cdot}}{m_{\cdot \cdot}} \frac{m_{\cdot 2}}{m_{\cdot \cdot}} = np_1.p_{\cdot 2} \end{aligned}$$

(ii)  $A*B \equiv A+B+A.B$  (Saturated model)

$$\log \mu_{ij} = \lambda + \lambda_i^A + \lambda_j^B + \lambda_{ij}^{AB} \quad i, j = 1, 2$$

with  $\lambda_1^A = \lambda_1^B = \lambda_{1j}^{AB} = \lambda_{i1}^{AB} = 0$ ,  
i.e linear predictor

		B	
		1	2
A			
1		$\lambda$	$\lambda + \lambda_2^B$
2		$\lambda + \lambda_2^A$	$\lambda + \lambda_2^A + \lambda_2^B + \lambda_{22}^{AB}$

i.e  $\hat{\lambda} = \log(m_{11})$

$$\hat{\lambda}_2^A = \log\left(\frac{m_{21}}{m_{11}}\right)$$

$$\hat{\lambda}_2^B = \log\left(\frac{m_{12}}{m_{11}}\right)$$

$$\hat{\lambda}_{22}^{AB} = \log\left(\frac{m_{22}m_{11}}{m_{12}m_{21}}\right) = \log(\text{observed odds-ratio})$$

### Lizard Data Analysis

Model	d.f.	Deviance	$X^2$
Height+Diameter	1	1.8477	
Height*Diameter	0	0	

*Estimates for the interaction model*

estimate	s.e.	parameter	
1	4.1111	0.1280	1
2	0.1796	0.1735	Height(2)
3	-0.3973	0.2019	Diameter(2)
4	0.3553	0.2622	Height(2).Diameter(2)

Note that this model reproduces the data and also the fitted log-odds ratio is 0.3553 giving a fitted odds-ratio of

$$\exp(0.3553) = 1.427$$

*Estimates for the main effects, or independence, model*

estimate	s.e.	parameter	
1	4.022	0.1148	1
2	0.3379	0.1296	Height(2)
3	-0.1883	0.1283	Diameter(2)

The fitted odds ratio is now zero and the change in deviance can be used to assess the significance of the null hypothesis that the log-odds ratio is zero, i.e. the odds ratio is 1

$$\text{change in deviance} = 1.848 \quad (p = 0.1740)$$

So this change in deviance is not significant, so we cannot reject the hypothesis that the odds-ratio is 1, i.e. diameter and height are independent.

## Lizard – analysis in R

```
# 2 by 2 table - lizard habitat data
y <- c(61, 41, 73, 70)
height <- factor(c(1, 1, 2, 2))
diam <- factor(c(1, 2, 1, 2))

lizard.dat <- data.frame(height, diam, y)
attach(lizard.dat)

# calculate observed odds ratio
61*70/(41*73)

# now set up log linear model
mod1<-glm(y ~ height*diam, family=poisson)
anova(mod1, test="Chisq")
summary(mod1)

# note that this model reproduces the data
# also the fitted log-odds ratio is 0.3553 giving a
# fitted odds-ratio of

exp(mod1$coef[4])

# the interaction term is not significant, so we
# cannot reject the hypothesis that the odds-ratio is 1,
# i.e. diameter and height are independent.

# refit simplest adequate model
# the main effects, or independence, model
mod2<-glm(y ~ height + diam, family=poisson)
anova(mod2, test="Chisq")
summary(mod2)
```

## 2-way Contingency Table

Table 3: Números de insetos coletados em armadilhas adesivas e sexados

Armadilha	Machos	Fêmeas	Totais
Alaranjada	246	17	263
Amarela	458	32	490
Totais	704	49	753

Fonte: Silveira Neto *et al.* (1976)

Pergunta: Há influência da cor da armadilha sobre a atração de machos e fêmeas dessa espécie?

Association measured by odds-ratio

Independence  $\implies$  odds-ratio = 1

$$\text{Observed Odds-ratio} = \frac{246 \times 32}{458 \times 17} = 1.01$$

**Is this significantly different from 1?**

### Traps Data Analysis

Model	d.f.	Deviance	$X^2$
Cor da armadilha + sexo	1	0.001254	0.001252
Cor da armadilha * sexo	0		0

*Estimates for the interaction model*

	estimate	s.e.	parameter
1	5.505	0.0638	1
2	0.622	0.0790	armcor(2)
3	-2.672	0.2508	sexo(2)
4	0.011	0.3104	armcor(2).sexo(2)

Note that this model reproduces the data and also the fitted log-odds ratio is 0.01098 giving a fitted odds-ratio of

$$\exp(0.01098) = 1.01$$

*Estimates for the main effects, or independence, model*

	estimate	s.e.	parameter
1	5.505	0.0624	1
2	0.622	0.0764	armcor(2)
3	-2.665	0.1478	sexo(2)

The fitted odds ratio is now zero and the change in deviance can be used to assess the significance of the null hypothesis that the log-odds ratio is zero, i.e. the odds ratio is 1

change in deviance = 0.00125 ( $p = 0.9117$ )

So this change in deviance is not significant, so we cannot reject the hypothesis that the odds-ratio is 1, i.e. diameter and height are independent.

## Traps – analysis in R

```
# 2 by 2 table - Traps y <- c(246, 17, 458, 32) armcor <-
factor(c(1, 1, 2, 2)) sexo <- factor(c(1, 2, 1, 2))

count.dat <- data.frame(armcor, sexo, y) attach(count.dat)

# calculate observed odds ratio 246*32/(17*458)

# now set up log linear model mod1<-glm(y ~ armcor*sexo,
family=poisson) print(sum(residuals(mod1, 'pearson')^2)) anova(mod1,
test="Chisq") summary(mod1)

# note that this model reproduces the data # also the fitted
log-odds ratio is 0.01098 giving a # fitted odds-ratio of

exp(mod1$coef[4])

# the interaction term is not significant, so we # cannot reject the
hypothesis that the odds-ratio is 1, # i.e. traps colour and sex
are independent.

# refit simplest adequate model # the main effects, or independence,
model mod2<-glm(y ~ armcor+sexo, family=poisson)
print(sum(residuals(mod1, 'pearson')^2)) anova(mod2, test="Chisq")
1-pchisq(deviance(mod2), df.residual(mod2)) summary(mod2)
```

## Simple 3-way Table

Random sample of diabetic patients classified by

- family history
- insulin dependence
- age at onset

Family history of diabetes

		Yes		No	
		Insulin Dep		Insulin Dep	
		Yes	No	Yes	No
Age at	< 45	6	1	16	2
Onset	$\geq 45$	6	36	8	48

Interested in the inter-relationship between the three classifying variables.

## Model Fitting

Model	Scaled Deviance	df
A+H+I	51.93	4
A*I+H	1.85	3
A*H+I	50.03	3
I*H+A	51.02	3
A*I+I*H	1.04	2
A*I+A*H	0.05	2
I*H+A*H	49.12	2
A*I+I*H+A*H	0.04	1
A*I*H	0	0

## Conclusions

Age and Insulin are independent of family history  
 $\implies$  can collapse table over History

		Insulin Dep		Total
		Yes	No	
Age at Onset	< 45	22	3	25
	$\geq 45$	14	84	98

$$\text{Odds-ratio} = \frac{(22/25)/(3/25)}{(14/98)/(84/98)} = \frac{22 \times 84}{3 \times 14} = 44$$

i.e. the odds of having insulin in the group younger than 45 years is 44 times that for the group older than 45 years.

Note that odds ratios in the individual tables are 36 and 48.

This collapsing over history does not distort the relationship between Insulin dependence and Age at onset.

*Cannot collapse over classifications that have significant interactions – Simpson's Paradox*

## Study of diabetic patients – analysis in R

```
# Study of diabetic patients
y <- c(6, 1, 16, 2, 6, 36, 8, 48)
age <- factor(c(1, 1, 1, 1, 2, 2, 2, 2))
hist <- factor(c(1, 1, 2, 2, 1, 1, 2, 2))
ins <- factor(c(1, 2, 1, 2, 1, 2, 1, 2))
lizard.dat <- data.frame(age, hist, ins, y)
attach(lizard.dat)

# now set up the log-linear model
mod1<-glm(y ~ age*hist*ins, family=poisson)
anova(mod1, test="Chisq")
summary(mod1)

# refit simplest adequate model
mod2<-glm(y ~ age + hist + ins + ins:age, family=poisson)
anova(mod2, test="Chisq")
summary(mod2)

# odds-ratio for age and insulin is
exp(mod2$coef[5])

# all other fitted odds-ratios are 1.
```

## Log-linear Models for 3-way Tables

Suppose classifying factors are A, B and C.

There are the following classes of models:

1. A\*B\*C
  - completely reproduces response pattern
2. A\*B+B\*C+C\*A
  - no 3-factor interaction model
3. A\*B+B\*C
  - A and C conditionally independent given B,  
$$A \perp C | B$$
    - (a) fitted odds-ratio for A,B same for all levels of C
    - (b) fitted odds-ratio for B,C same for all levels of A
    - (c) fitted odd-ratio for A,C is 1 for all levels of B, but marginal odds ratio is not 1
4. A\*B+C
  - joint distribution of A and B is the same for all levels of C  $\Rightarrow$  can collapse over C.
5. A+B+C – mutual independence model

**Binomial Logit & Poisson Log-linear Models**

Gender	Response		
	No	Yes	
Male	20	12	32
Female	14	30	44
	34	42	76

Interested in the gender difference for the proportion responding “Yes”.

### Tabelas com Resposta Binomial

Duas categorias de resposta: sim/não, sucesso/falha etc

O interesse está em saber como a proporção que respondeu SIM depende de outras covariáveis.

#### Especificação:

1. Dados:  $r_{i2}, m_i, \mathbf{x}_i$ ,  $i = 1, \dots, n$ , onde  $r_{i2}$  representa o número de sucessos (SIM),  $m_i = r_{i+}$  é o número de indivíduos, e  $\mathbf{x}_i$  são variáveis explanatórias (por exemplo, fatores de classificação etc).
2. Modelo probabilístico:

$$R_{i2} \sim \text{Bin}(m_i, \pi_i).$$

3. Função de ligação: logit

$$\text{logit}(\pi_i) = \log\left(\frac{\pi_i}{1 - \pi_i}\right) = \eta_i = \boldsymbol{\beta}' \mathbf{x}_i$$

## Resultados do Modelo Binomial

- (i) Modelo minimal = modelo nulo:  $\eta_i = \text{logit}(\pi_i) = \theta_0$   
 Deviance = 7,131 com 1g.l.

$$\text{logit}(\hat{\pi}) = 0,2113 \Rightarrow \hat{\pi} = 0,5526 = \frac{42}{76}$$

- (ii) Modelo para efeito de sexo:

$$\eta_i = \text{logit}(\pi_i) = \beta_0 + \text{sexo}_i$$

$$\text{logit}(\pi_1) = \theta$$

$$\text{logit}(\pi_2) = \theta + \theta_1$$

Deviance = 0 com 0g.l.

Parâmetro	Estimativa	Erro padrão
1	-0,5108	0,3651
sexo(2)	1,273	0,4879

$$\text{logit}(\hat{\pi}_H) = -0,5108$$

$$\Rightarrow \hat{\pi}_H = 0,375 = \frac{e^{-0,5108}}{1 + e^{-0,5108}} = \frac{12}{32}$$

$$\text{logit}(\hat{\pi}_M) = -0,5108 + 1,273 = 0,7622$$

$$\Rightarrow \hat{\pi}_M = 0,682 = \frac{30}{44}$$

### Tabelas com Resposta Poisson log-linear

Tratar as caselas da tabela como variáveis Poisson independentes, isto é  $R_{ij} \sim \text{Pois}(\mu_{ij})$ , fixados os totais marginais de sexo (reproduz os  $m_i$  da binomial) e com classificação cruzada para tipo de resposta.

#### Especificação:

1. Dados:  $r_{ij}, \mathbf{x}_{ij}$ , em que  $r_{ij}$  representa a contagem na célula  $ij$  e  $\mathbf{x}_{ij}$  são variáveis explanatórias (por exemplo, fatores de classificação etc).
2. Modelo probabilístico:

$$R_{ij} \sim \text{P}(\mu_{ij}).$$

3. Função de ligação: logarítmica

$$\log(\mu_{ij}) = \eta_{ij} = \boldsymbol{\beta}' \mathbf{x}_{ij}$$

## Resultados do Modelo Poisson

(i) Modelo minimal (reproduz as margens):

$$\eta_{ij} = \log(\mu_{ij}) = \alpha_0 + sexo_i + resp_j$$

Resposta

Sexo	1	2
1	$\alpha_0$	$\alpha_0 + \beta_0$
2	$\alpha_0 + \gamma_0$	$\alpha_0 + \beta_0 + \gamma_0$

$$\theta_0 = logit(\pi_1) = \log \mu_{12} - \log \mu_{11} = \beta_0$$

$$\theta_0 = logit(\pi_2) = \log \mu_{22} - \log \mu_{21} = \beta_0$$

Deviance = 7,131 com 1g.l.

(ii)  $\eta_{ij} = \log(\mu_{ij}) = \alpha_0 + sexo_i + resp_j + sexo.resp_{ij}$

Resposta

Sexo	1	2
1	$\alpha$	$\alpha + \beta$
2	$\alpha + \gamma$	$\alpha + \beta + \gamma + \delta$

$$\theta = logit(\pi_1) = \log \mu_{12} - \log \mu_{11} = \beta$$

$$\theta_1 = logit(\pi_2) - logit(\pi_1) =$$

$$(\log \mu_{22} - \log \mu_{21}) - (\log \mu_{12} - \log \mu_{11}) = \delta$$

Deviance = 0 com 0g.l.

```
# Fitting Binomial Logit model
y1 <- c(12, 30)
m <- c(32, 44)
sex1 <- factor(c(1, 2))
Bin.Pois1 <- data.frame(sex1, m, y1)
attach(Bin.Pois1)

# now define binomial logit model
resp1 <- cbind(y1, m-y1)
modBin <- glm(resp1 ~ sex1, family=binomial)
anova(modBin, test="Chisq")
summary(modBin)

# calculate observed odds ratio
exp(modBin$coef[2])

# now fit the data using Poisson log-linear models

y2 <- c(20, 14, 12, 30)
resp2 <- factor(c(1, 1, 2, 2))
sex2 <- factor(c(1, 2, 1, 2))

attach(Bin.Pois2)

#now define the Poisson model - independence model
modPois<-glm(y2 ~ resp2+sex2, family=poisson)
anova(modPois, test="Chisq")
summary(modPois)
# notice that the marginal totals have been reproduced

# interaction model
modPois<-glm(y2 ~ resp2*sex2, family=poisson)
anova(modPois, test="Chisq")
summary(modPois)

# calculate observed odds ratio
20*30/(12*14)
exp(modPois$coef[4])
```

### Theoretical Relationship between Binomial and Poisson

Denote table entries by  $R_{ij}$ ,  
 $(i = \text{gender}, j = \text{response})$

If  $R_{ij} \sim \text{Pois}(\mu_{ij})$ , independently and we constrain the gender totals, i.e. consider

$$R_{i+} = R_{i1} + R_{i2}, \quad i = 1, 2$$

to be fixed, then

$$R_{i2}|R_{i+} \sim \text{Binomial}(R_{i+}, p_i)$$

where

$$p_i = \frac{\mu_{i2}}{\mu_{i1} + \mu_{i2}}$$

Note

$$\begin{aligned} \text{logit}(p_i) &= \log \left( \frac{\mu_{i2}}{\mu_{i1}} \right) \\ &= \log(\mu_{i2}) - \log(\mu_{i1}) \end{aligned}$$

i.e. logit of YES response is the response effect on the Poisson log-linear scale

## Contingency tables and log-linear models

## Pneumoconiosis in Coalminers

From J.A.Ashford, "An approach to the Analysis of Data for Semi-quantal Responses in Biological Response".  
Biometrics 15: 573-581 1959

Coalminers classified by radiological examination into 3 categories of pneumoconiosis (normal, mild, severe) by period of time spent at the coalface (mid-points of class interval).

Years	None	Mild	Severe	Total
5.8	98	0	0	98
15.0	51	2	1	54
21.5	34	6	3	43
27.5	35	5	8	48
33.5	32	10	9	51
39.5	23	7	8	38
46.0	12	6	10	28
51.5	4	2	5	11

### Relationship between Multinomial and Poisson

If  $N_j \sim \text{Pois}(\mu_j)$ ,  $j = 1, \dots, k$ , independently, then,

$$N_1 + N_2 + \dots + N_k = N \sim \text{Pois}(\mu_1 + \mu_2 + \dots + \mu_k)$$

and

$$\begin{aligned} & P(N_1 = n_1, N_2 = n_2, \dots, N_k = n_k \mid N = n) \\ &= \frac{P(N_1 = n_1, N_2 = n_2, \dots + N_k = n_k)}{P(N = n)} \\ &= \frac{\prod_{j=1}^k P(N_j = n_j)}{P(N = n)} = \frac{n!}{\mu^n e^{-\mu}} \prod_{j=1}^k \frac{\mu_j^{n_j} e^{-\mu_j}}{n_j!} \\ &= \frac{n!}{n_1! \dots n_k!} p_1^{n_1} p_2^{n_2} \dots p_k^{n_k} \end{aligned}$$

with  $p_j = \frac{\mu_j}{\mu}$ .

## Multinomial Response Data

Categorical response variable with  $k$  categories, labeled  $1, 2 \dots, k$ .

Multinomial distribution with  $n_i$  outcomes type  $i$  and  $\sum_{i=1}^k n_i = n$  has probabilities

$$P(n_1, n_2 \dots, n_k) = \frac{n!}{n_1! n_2! \dots n_k!} p_1^{n_1} p_2^{n_2} \dots p_k^{n_k}$$

where  $\sum_{i=1}^k p_i = 1$

Multinomial Logits - use 1st category as reference

$$\begin{aligned}\theta_j &= \log\left(\frac{p_j}{p_1}\right) = \log\left(\frac{\mu_j}{\mu_1}\right) \quad j = 2, \dots, k \\ \theta_1 &= 0\end{aligned}$$

No real restriction in using 1st category since

$$\theta_j - \theta_i = \log\left(\frac{p_j}{p_1}\right) - \log\left(\frac{p_i}{p_1}\right) = \log\left(\frac{p_j}{p_i}\right)$$

## Multinomial Logit Models

Expl. var.	1	...	k	Total
$x_1$	$n_{11}$	...	$n_{k1}$	$n_{.1}$
$x_2$	$n_{12}$	...	$n_{k2}$	$n_{.2}$
...	...	...	...	...
$x_m$	$n_{1m}$	...	$n_{km}$	$n_{.m}$

For  $m$  multinomial observations

$$\mathbf{n}_i = (n_{1i}, n_{2i} \dots n_{ki})$$

with explanatory variables  $\mathbf{x}_i$  we have  
multinomial logit models

$$\theta_{ji} = \mathbf{x}_i^T \boldsymbol{\beta}_j$$

with  $j = 2, \dots, k$  (categories) and  $i = 1, \dots, m$  (observations).

## Poisson Log-linear Model

Modelling the individual counts  $n_{ij}$  as Poisson random variables with means  $\mu_{ij}$  the Poisson/multinomial relationship gives us

$$\theta_{ji} = \log\left(\frac{p_{ji}}{p_{1i}}\right) = \log\left(\frac{\mu_{ji}}{\mu_{1i}}\right) = \mathbf{x}_i^T \boldsymbol{\beta}_j$$

or

$$\phi_{ji} = \log(\mu_{ji}) = \psi_i + \mathbf{x}_i^T \boldsymbol{\beta}_j$$

where  $j = 2, \dots, k$ ,  $\boldsymbol{\beta}_1 = 0$  and  $\psi_i = \log(\mu_{1i})$  are a set of nuisance parameters.

## Fitting via Log-Linear Models

To fit these Poisson models we need to

- include a full model in the classifying factors to give the nuisance parameters  $\psi_i$  and reproduce the marginal multinomial totals
- include a response factor ( $k$  levels) to reproduce the overall response pattern;
- $\beta_j$  are the coefficients of the *interaction* of the  $j$ th level of the response with the explanatory variables  $x$ .

### Advantages:

- (i) a multivariate problem is converted to a univariate one.
- (ii) standard log-linear modelling software can be used.

### Disadvantages:

- (i) requires estimation of many nuisance parameters;
- (ii) can be slow for large tables.

## Fitting in R

- Define a response factor with  $k$  levels corresponding to the multinomial response categories;
- Model the cell counts as Poisson variables with log link function;
- Set up model in classifying variables to index multinomial observations – reproduce the marginal multinomial totals

$\eta = \text{var}$

- Fit the “null” multinomial model – overall pattern

$\eta = \text{var} + \text{resp}$

- Fit models of interest

$\eta = \text{var} + \text{resp} + \text{resp} : \text{var}$

-  $\beta_j$  is the coefficient of the interaction of the  $j$ -th category response with the explanatory variables  $x$

- standard errors and deviances are also correct.

## Ordinal Logistic Regression

**Aim:** modelling an ordered categorical variable

- response variable  $Y$  – ordered categories
- use linear function of explanatory variables
- can include categorical variables
- model **cumulative logits** of response probabilities

$$\text{logit}(\gamma_{ij}) = \log \left( \frac{Pr(Y_i \leq j | \mathbf{x}_i)}{Pr(Y_i > j | \mathbf{x}_i)} \right)$$

- the cumulative logit model is given by

$$\text{logit}(\gamma_{ij}) = \theta_j - \mathbf{x}_i^T \boldsymbol{\beta}$$

where  $\theta_j$  may be thought of as category cut-points for an underlying continuous latent variable.

$\mathbf{x}_i$  are the covariates and  $\boldsymbol{\beta}$  the parameter vector.

- gives proportional odds model;  
e.g. for a simple model

$$\text{logit}(\gamma_{ij}) = \theta_j - x_i^T \beta$$

the difference in two logits is a *cumulative odds ratio* and

$$\begin{aligned} & \text{logit}(\gamma_{rj}) - \text{logit}(\gamma_{sj}) \\ &= \log \left( \frac{Pr(Y_r \leq j|x_r)/Pr(Y_r > j|x_r)}{Pr(Y_s \leq j|x_s)/Pr(Y_s > j|x_s)} \right) \\ &= -\beta(x_r - x_s) \end{aligned}$$

- negative sign for  $\beta$  associates increasing values of  $Y$  with increasing values of  $\mathbf{x}$ .

## Log-Linear models for Ordered Data

### Linear by Linear Association

Another possible approach is to assign scores to any ordered response. For a 2-way table ( $A \times B$ ,  $A$  with  $a$  levels,  $B$  with  $b$  levels), assigning scores  $u_i$  and  $v_j$  to the rows and columns gives an ordered interaction model

$$\log(m_{ij}) = \lambda + \lambda_i^A + \lambda_j^B + \gamma u_i v_j$$

with  $ab - a - b$  degrees of freedom  $\gamma = 0$  corresponds to the independence model.

Special case of the full interaction (saturated) model.

Odds-ratio interpretation:

$$\log \left( \frac{m_{hj} m_{ik}}{m_{hk} m_{ij}} \right) = \gamma(u_i - u_h)(v_k - v_j)$$

Considering adjacent cells gives local odds ratios

$$\theta_{ij} = \frac{m_{i,j}m_{i+1,j+1}}{m_{i,j+1}m_{i+1,j}}$$

and so

$$\log \theta_{ij} = \gamma(u_{i+1} - u_i)(v_{j+1} - v_j)$$

Taking integer scores gives

$$\log \theta_{ij} = \gamma$$

the *uniform association model*.

Easily fitted as a log-linear model.
